Social Robots as Agents of Behaviour Change for Developing countries: Influencing Handwashing Behaviour

My research vision is to develop low-cost high impact social robotic applications for people in developing countries. Human-robot Interaction (HRI) research is predominant in the developed world and having real world deployments of social robots is rare, where more than 75% of research is done in a lab without considering real world impact. Influence and perception of social robots has barely been investigated for subjects from rural populations in developing countries where social robots could potentially create a positive impact in their lives. For social robots to be effective in developing countries it is important to understand how people rationalise their behaviour and how social robots can influence their behaviour in a positive manner. This fellowship aims to address the technological challenges of using social robots effectively with rural populations in developing countries. I have identified a specific use-case where social robots could create a very high impact in developing countries, hand hygiene. In developing countries diarrhoea and respiratory infections are the two biggest causes of child mortality. By developing an intervention such as hand washing with soap, child mortality can be reduced by 40%. In this fellowship I propose a new approach in hand hygiene promotion and education using social robots and measure its impact by systematic empirical studies in rural schools in India. The outcomes of this research could contribute towards informing design decisions for social robotic applications that seek to address the underserved populations of the world.

Section 3 - Applicant Career Summary

Title of Current Position

Please state the title of your current position.

Research Associate

Current Employer

Please enter the official organisation name of your current employer.

University of Glasgow

Current Department

Institute of Neuroscience & Psychology

Current Position Start Date

Please enter the date when your current position started.

01 April 2016

Current Position End Date

Please enter the date when your current position is expected to finish.

31 October 2020

Date of First Post-Doctoral Research Position

01 April 2016

PhD Award Date

Please enter the date that you were awarded your PhD.

01 December 2015

PhD Institution

State the name of the institution where you were awarded or are completing your PhD.

Heriot-Watt University

Personal Statement

Please provide a personal statement detailing your research career to date including prizes and achievements, and your career and research aspirations in the long term.

I am a Roboticist and built my first social robot during my Bachelor's in Electronics and won national level robotics competitions at Asia's largest model presentation contest also amassed immense media publicity across India. I was awarded a scholarship for my second Masters from Jacobs University Bremen M.Sc. "Smart Systems". I completed my PhD from Heriot-watt University in Edinburgh in human-robot interaction investigating social verbal feedback strategies to influence the acceptance by users towards a social robot. I have worked on multiple European Union projects involving social robots in workplaces, child-robot interaction, public spaces, rural environments. My key research expertise is to analyse and understand how people interact with robots, build robotic systems that can interact effectively and influence human behaviour using user-centred design approaches. I have published 42 (18 as first author) peer-reviewed papers and journal articles internationally. I have reviewed numerous journal articles and conference papers. I was the finance chair for the IEEE RO-MAN conference in 2014 and a special session chair in 2019. I was speaker at Pint of science, "Robots, it makes sense!", Glasgow, 2017. I also contributed in the application (specifying robotics lab equipment) for a successful grant of £6 million of UK government funding for Edinburgh Centre for Robotics in 2014. I won the best one-page statement award on "what future research is required for personal robotics and why?" at the (TAROS) Towards Autonomous Robotic Systems conference, 2009. I have recently moved to Psychology department to learn research methodologies from social sciences perspective.
I have always pursued independent research ideas that can cause a real impact on people's lives and improve it through their interaction with robots. This constant urge motivated me to carry out human-robot research in rural populations breaking the traditional research in my field. I took 2 months absence of leave and secured a funding from Scottish Informatics and Computer Science Alliance for researcher exchange funding of £3500 to travel and collaborate with Amrita University in India in November 2017. This was first of its kind human-robot interaction research conducted with rural subjects in Indian villages to study user perception and acceptance of technology interventions. The research resulted in 2 publications and global media coverage including 14 online media articles like The BBC, The Telegraph, IEEE spectrum and 4 Scottish regional news papers. I have organised the inaugural workshop on the topic "Social robots and artificial agents for developing countries: Challenges and opportunities" at 2019 RO-MAN conference. My interdisciplinary skills with electronics and computer science and the experience I have gained from developing and deploying social robots makes me an ideal candidate to undertake this research. This prestigious Royal society fellowship will allow me to broaden my knowledge and skills and help to establish myself as a world-leading and a pioneering researcher in social robotics developing and engineering innovative solutions for rural communities in developing countries. After the fellowship I will seek to lead a multidisciplinary research group on funded projects to advance social robotics research for developing countries.

Applicant Career History

Please list all of your appointments since your PhD and the dates in reverse chronological order, stating if part-time (and percentage part-time) when necessary.

Research Associate
University of Glasgow, Glasgow, UK
01-04-2016-current

Research Associate
Heriot-Watt University, Edinburgh, UK
01-10-2008 - 31-03-2016

Applicant Research Funding

Please list all your current and previous research funding in reverse chronological order.

Lord Kelvin Adam Smith (LKAS) Fellowship funding £100,000 to supplement this application, 2019.

Travel grant of £3,500 from SICSA - Scottish Informatics and Computer Science Alliance for post doctoral and Early Career Researcher Exchange, 2017.

Contributed in defining and procuring robotics lab equipment for Heriot-Watt University, Edinburgh Centre for Robotics, 2014 (successful grant £6 million of UK government funding)

Section 4 - Research Proposal

Start Date

Please enter the proposed start date of the project.

01 October 2020

End Date

Please enter the proposed end date of the project.

30 September 2025

Project Title

Please give the full title of your proposed project.

Social Robots as Agents of Behaviour Change for Developing countries: Influencing Handwashing Behaviour

Keywords

Provide up to 5-10 key words that could be used to describe your research, which will aid with identifying the most appropriate peer reviewers.

Human-robot interaction, social robotics, handwashing, educational robots, persuasive technologies, gamification

Subject Group

Computer Science

Subject Area

- ☑ Computer Engineering (incl. software)
- ☑ Control (incl. robotics)
- ☑ Experimental Psychology
- ☑ Development and Control of Behaviour
- ☑ Artificial Intelligence
- ☑ Machine Learning
- ☑ Vision
- ☑ Human-computer interaction

Abstract

Please provide a scientific summary of your proposed project. This should be a summary of your research proposal, briefly outlining the background and summarising the aims of your project.

The aim of this fellowship is to develop social robots as tools for persuasive technologies that can autonomously interact with people and effect positive change on their behaviour. This research is addressing a very important issue in public health in developing countries, hand hygiene compliance, which could reduce germ transmission, save public health costs and decrease infection-related absenteeism in schools. According to World Health Organisation, Handwashing With Soap (HWWS) has the potential to save more than a million lives a year. Consequently, HWWS is included in the UN's sustainable development goals Target 6.2 for sanitation and hygiene. Existing practices for influencing handwashing behaviour in developing countries face three major challenges (i) they are very resource intensive, (ii) complex to measure/monitor compliance at scale and (iii) rarely result in positive, sustained behaviour change over long-term. Hence there is need for a multi-disciplinary and innovative approach for influencing sustainable handwashing behaviour change. However none of the previous hand hygiene interventions have considered the use of interactive technological interventions using social robots. Social robots can, for example, encourage, remind, educate, give real-time feedback, observe and monitor hand washing behaviour.

The key research questions to be addressed in this fellowship are (i) how can social robots achieve sustainable handwashing behaviour change? (ii) what interaction design strategies (verbal and non-verbal) are the most effective in influencing handwashing behaviour? In order to achieve the goal of this research, there is a need to develop the autonomous capabilities, which is a significant scientific and technical step in this research. The research methodology will involve: (i) a multi-disciplinary approach combining

behavioural science and strategies of human factors engineering into the behaviour of the social robot, (ii) user-centered iterative design approach within the target population (iii) conduct empirical studies to investigate the influence of a social robot on handwashing behaviour. This research will encompass an approach based on gamification principles and multimodal affective feedback strategies from the social robot. I will initially target India which has the world's largest rural population of 850 million with only 15% HWWS prevalence rate. The annual net costs to India from not washing hands are estimated at US $ 23 billion and for example a national handwashing program in India could provide an estimated 92-fold return on investment.

Lay Summary

My research vision is to develop low-cost high impact social robotic applications for people in developing countries. Human-robot Interaction (HRI) research is predominant in the developed world and having real world deployments of social robots is rare, where more than 75% of research is done in a lab without considering real world impact. Influence and perception of social robots has barely been investigated for subjects from rural populations in developing countries where social robots could potentially create a positive impact in their lives. For social robots to be effective in developing countries it is important to understand how people rationalise their behaviour and how social robots can influence their behaviour in a positive manner. This fellowship aims to address the technological challenges of using social robots effectively with rural populations in developing countries. I have identified a specific use-case where social robots could create a very high impact in developing countries, hand hygiene. In developing countries diarrhoea and respiratory infections are the two biggest causes of child mortality. By developing an intervention such as hand washing with soap, child mortality can be reduced by 40%. In this fellowship I propose a new approach in hand hygiene promotion and education using social robots and measure its impact by systematic empirical studies in rural schools in India. The outcomes of this research could contribute towards informing design decisions for social robotic applications that seek to address the underserved populations of the world.

Research Proposal

You can either detail your research proposal within this application form, or alternatively upload it as a PDF file. PDF files must be no longer than 3 sides of A4, portrait orientation, be titled and the text size cannot be smaller than Arial size 10.

Your research proposal should provide a general description of the proposed research to be carried out. This should include, but is not limited to, the following:

- **clear specification of the context, research objectives and expected outputs of the proposed study;**
- **description of the methodology to be used, including data analysis;**
- **an indication of the milestones and timescales**

Please specify your preferred method for detailing your research proposal.

Host Organisation

Please select the organisation where the award will be held from the drop down list below.

University of Glasgow

Host Department

Computing Science

Justification for Choice of Host Organisation

This fellowship will take place in the School of Computing Science (SoCS) at the University of Glasgow (UOG). UOG, is a member of the prestigious “Russell Group” of leading UK research universities, is 55th in the QS World Ranking 2014, employs more than 6,000 people (2,000 active researchers) and has annual research income of more than £181M. The School of Computing Science (SoCS) is rated in the UK’s top 10 for research, according to the 2008 “Research Assessment Exercise” and is in the top 100 in the QS World University Rankings by Subject 2014. Current research funding amounts to more than £6M in SoCS. The Social Robotics group at the school of Computing Science is collaborative and interdisciplinary, working closely with other schools including Psychology and the Institute of Health and Wellbeing. The SoCS has recently been awarded a Centre for Doctoral Training (CDT) together with the Institute for Neuroscience and Psychology to train a cohort of 50 PhD students on Socially Intelligent Artificial Agents. This research on the use of social robots for public health in the developing world fits within the GIST (Glasgow Interactive Systems) group at computing science department. GIST aims to create and use novel, interactive systems to better understand, entertain, protect and support humans in their everyday lives. I have two mentors from UOG, from Institute of Health and Wellbeing Prof Sally Wyke, Deputy Director and Dr Katie Robb. They are experts in applying interdisciplinary social science theory, developing and evaluating interventions for health and wellbeing appropriated to context and culture. In addition, this research will also benefit from connections with the Glasgow Centre for International Development (GCID), a pan-University network that aims to create an interdisciplinary, collaborative and supportive environment for researchers working with collaborators in low and middle income countries. I have secured an additional £100,000 funding from UOG's Lord Kelvin Adam Smith (LKAS) Fellowship funds for a PhD student and buy additional equipment, video annotations, travel support for conducting field studies to supplement this proposed research. UOG provides an excellent research environment to carry out my research in the most effective manner.

Outline of Data Management and Data Sharing Plan

If the proposed research will generate data that is of significant value to the research community, then please provide details of your data management and sharing plan.

The data generated from this research will comprise of questionnaires in excel files, image and video data from field studies. All data will be anonymised and I will use robust security measures to protect participants’ data, such as encryption, and store data securely on the University’s servers for a maximum period of five years following the project. I will use automated software to pixelate faces (using Adobe After Effects) and remove audio on recorded footage after analysis has been performed. Data will be stored on encrypted hard drive with password protection. All data storage and provision will be compliant with GDPR procedures as implemented at UOG. The video and image data collected from handwashing (no faces, hand movements only) will be valuable to train machine learning algorithms on hand gesture recognition for the wider community and will be made available on https://www.openml.org/.

Section 5 - Use of Animals in Research

Does your proposal involve the use of animals or animal tissue?

⦿ No

Section 6 - Use of Human Patients and Tissue

Does your proposal involve the use of human patients or tissue?

⦿ No

Section 7 - ODA Compliance

Please indicate if you think your proposed research meets the remit of the Global Challenges Research Fund.

⦿ Yes

How is your proposal directly and primarily relevant to the development problems of these countries?

Handwashing with soap (HWWS) is included in the United Nations (UN) sustainable development goals Target 6.2 for sanitation and hygiene. Every year, nearly 443 million school days are lost due to water and sanitation related diseases in developing countries. My proposed research idea reflects a low-cost method with the potential to increase hand hygiene compliance, which could reduce germ transmission, save public health costs and decrease infection-related absenteeism in schools. My research if scaled could also contribute towards meeting UN's sustainable development goals targets around sanitation, hygiene, education, nutrition and child survival in developing countries. Social robots could have a great potential to serve a supportive role in large scale health interventions both as active agents of behaviour change as well as objective assessors of various indicators of health and hygiene. I believe it is important to understand the scientific and interaction design challenges of introducing robotic solutions in a real life rural setting. The UN's sustainable development goals also relate to bridging the digital divide, making technology more accessible to all users rather than a privileged few in developed countries. My research helps identifying a valuable and viable use case for social robots in rural populations.

How do you expect that the outcome of your proposed activities will promote the economic development and welfare of a country or countries on the DAC list?

India, a lower middle income country, has the world's largest rural population of approximately 850 million, about 30% under 14 years of age (270 million), and only 15% of the entire population practices handwashing with soap. Townsend et al. in a study, (https://doi.org/10.1111/tmi.12808, 2017) reports that the DALYs (Disability Adjusted Life Years, calculated as the sum of the Years of Life Lost due to premature mortality and the years lost due to Disability) due to diarrhoea in India amounted to 29.77 million, 14.63 million of which were for infants under 5 years of age and 3.14 million for children 5–14 years of age. The economic loss to India from the 29.77 million DALYs due to diarrhoea is estimated at US$ 47.157 billion (US$ 23.169 billion for children under 5 years and US$ 8.955 billion for children 5–14 years). Since the target age group for the proposed intervention is primary school children aged between 5-11, even with a rough estimate considering the above figures the economic loss for that age group is huge. The population contracting diarrhoea due to not washing their hands is estimated at 90.4% and handwashing with soap can reduce the risks by 40% (preventable costs upto US$ 3-4 billion for age group 5-14). We are not targeting the entire population in our research, but the potential cost savings if the intervention is sustainable can produce huge economic savings. My research idea also compliments the national campaign launched by Indian government "Swachh Bharat – Swachh Vidyalaya" (Clean India – Clean Schools) working to improve water, sanitation and hygiene (WASH) services and practices across India. I shall pursue to take this technology to other countries, I am an affiliate member of Sustainable Futures in Africa (SFA) network

which spans across countries like Uganda, Botswana, Nigeria and Malawi.

DAC Country list

☑ India

Section 8 - Financial Details

Please define the proposed budget for your Fellowship in the table below, ensuring that you provide values at 100%:

Period Group	Item Type	Item	Field	£
2020 - 2021	Basic Salary	Basic Salary	Cost	£40,681.46
	London Weighting Allowance	London Weighting	Cost	£0.00

	Indirect costs	Indirect costs	Cost	£280,290.00
	Estate costs	Estate costs	Cost	£82,545.00
	Other costs	Other costs	Cost	£0.00
Total			**Cost**	**£713,321.46**

Justification for Research Expenses

1) Requesting £8,000 for Consumables (inc. fieldwork), i anticipate costs associated with conducting field studies, mainly for year 1, 3 and 4 for building prototypes, video annotations/editing software, 3d printing.

2) Requesting £7,000 for two summer student interns for year 2 and 4 to carry out video annotations, transcribe and translate interviews on data collected from field studies also some coding tasks are anticipated. Public engagements such as running workshops at schools in India and Glasgow for hand hygiene awareness games using the social robot.

3) Requesting £27,000, Travel (inc. subsistence) as this research will require me to travel multiple times to India to conduct field studies and conference travel. I plan to spend 2 months in India during field studies in Year 1, 3 and 4. The travel costs are expected to be higher due to remote locations where field studies will be conducted. Also having student volunteers to assist with the field studies is necessary where you need volunteers to speak the local language in order to conduct interviews with the participants. From my previous experience doing field studies in small villages, researchers need to stay in remote accommodations for a few days in order to complete the study.

4) Equipment £13,000, Electronic components for building the prototype and other hardware required for the system. Powerful computer with GPU for vision processing algorithms, cameras, hard drives to store video data, wireless motion sensors.

5) PhD Studentship (£19,336) for the first year, the remaining (three years, £59,849) costs associated with the studentship, (fees at UK level and stipend) will be covered by the University LKAS (Lord Kevin Adam Smith) leadership funds. Further £8,000 have been secured through the LKAS fund to support the a PhD student at Amrita University for 4 years.

Section 9 - Applicant Declaration

Social Robots as Agents of Behaviour Change for Developing Countries: Influencing Handwashing Behaviour

1 Overview:

In this fellowship I will develop a low-cost social robot to create a step change in the efficacy of Handwashing With Soap (HWWS). HWWS is one of the most cost-effective public health interventions in reducing the burden of global infectious diseases by upto 40%.[1] Previous research suggests that hygiene promotion programmes mostly focus on educating people about health, germs and disease often using tools such as games, radio/TV campaigns, leaflets, comic books, songs, posters, leaflets and charts.[2,3] Such methods can be very resource intensive to monitor at scale, measurements are unreliable due to self-reporting and these approaches rarely result in positive, sustained behaviour change.[4] Evidence suggests the physical setting where the handwashing behaviour should take place by placing attention grabbing cues and visual reminders can lead to more successful interventions.[2,5] In regards to behavioural science it is known that people change their behaviour when they know they are being watched, also known as the *"Hawthorne Effect"*.[6] The physical presence of a robot could impact human perception and influence behaviour as humans have a tendency to anthropomorphize social robots.[7] Handwashing interventions in schools are an effective way of reaching children and teaching them the habit of handwashing at a young age.[5] I have formed a collaboration with Amrita University and their team in India,[8] who are engaged in technology interventions and community development activities in over 142 villages in India. Given the ambition and the risks in this research vision, I conducted an independent research pilot project in collaboration with Amrita University in India. I led a team of 4 students and developed and deployed a proof-of-concept a low-cost ($\approx$ US $ 100) prototype social robot which was remotely controlled (not autonomous) in a rural village school in India in March 2019 (see figure 1). The pilot study showed encouraging results: a staggering 40% increased level of HWWS and with a better handwashing technique.[9,10]

Figure 1: Image Left: Prototype Robot Design; Image Right: The robot attached on the wall near the water tap encouraged around 100 children to follow the correct hand washing steps via a poster on the wall.[9,10]

I will leverage this proof-of-concept and develop the technology further. The main objectives of this research are (i) to evaluate which interaction and design strategies are more effective to engage and influence handwashing with children in schools, (ii) to develop the autonomous capabilities for the social robot for perception and synthesis of behaviours, and (iii) conduct field studies to measure the impact and sustainability of intervention. The approach will focus on investigating the use of gamification which has shown promising results in technology based education[11] and health related contexts.[12,13] Gamification is the process of including game like elements that could motivate and influence human behaviour to enhance learning. However there is no evidence to suggest that gamification strategies are effective to increase hand hygiene compliance for children from rural backgrounds in developing countries using social robots. I aim to carry out interventions using the social robot in 15-20 schools overall (target reach approximately 2,000-3,000 children, aged 5-11 years) across different states in India during the research period. My plan for the Fellowship is broken down into 4 workpackages (WPs), the outcome of each WP informs the design strategy for the next WP. There is also possibility for WPs to run in parallel to some extent as some activities can be carried out independently. I expect to publish the findings from the outcomes generated from each WPs in relevant and leading conferences and journals.

2 Programme of Work and Methodology

2.1 WP1- Evaluation of interaction and design strategies for the social robot, *Year 1*

The year 1 goal is to evaluate the interaction design strategy necessary to address the scientific challenges in the context of this research by means of an informed design process. I will conduct user studies by using Wizard of Oz (WoZ) which is a common and important technique in social robotics research to get initial impressions about interaction designs.[14] The aim of the study will be to investigate the following: (1) how gamification using the social robot influences handwashing behaviour (2) how affective feedback (emotions) expressed through verbal and non-verbal behaviour of the robot influence children's behaviour, and (3) what important perceptual cues that need to be recognised and handled. Examining these characteristics can be useful while incorporating the findings into the design of autonomous system (WP2). Some studies have shown the use of emotional drivers significantly increased HWWS, for example disgust (the desire to avoid and remove contamination) using an animated film/video.[2,15] However, the use of emotional drivers using affective feedback by means of social robots in hand hygiene context has not be explored before. My previous work with affective feedback

has shown promising results with social robots as tutors.[16] However more empirical research is required to determine whether both extrinsic and intrinsic motivation to wash hands can be influenced by gamification combined with affective feedback strategies. For affective expressiveness, the social robot will also have eye movement to track users and display emotions e.g. happy, sadness, disgust. A screen using a mobile phone to display graphical mouth to display smiles, frowns and hand hygiene educational videos and a loud speaker for sounds and speech synthesis. Gamification strategies can include for example, if the children wash their hands effectively, a time based graphics will be shown on the screen (e.g. balloon bursts or a rocket fires), and behaviours using both verbal and non-verbal feedback from the robot will be systematically investigated. This research will be supervised by Dr Mary Ellen Foster from the University of Glasgow, an expert in real-world deployment of social robots especially on verbal and non-verbal feedback strategies. A parallel-design, randomised cluster experiment will be performed using the above approach near the handwashing station in 3 rural schools in India.

Mixed research methods i.e. qualitative and quantitative data will be collected using video recordings of the interaction and questionnaires. All data will be made anonymous conforming to privacy and ethical approval in India and University of Glasgow ethics committee. Informed and written consent will be obtained from the school authorities and children's parents before recording, and only research staff would have access to the data. The video data will be analysed to determine behaviour cues and social signals from the users such as proxemics (i.e. coming close to the robot), facial expressions (i.e., smiles), oculesic behaviour i.e. eye contact (frequency, duration), speech utterances, and body movements (gestures, head pose) to measure the degree of engagement with the robot. Annotations using BORIS, an event logging software for video/audio coding and live observations will be performed.[17] Videos of participants washing hands will also be recorded from a top camera. In addition, qualitative feedback will be obtained from focus groups using questionnaires to get detailed perception about the design features of the robot using Smileymeter, a visual likert scale developed by Read et al.[18] used for user studies in child computer interaction. The questionnaires will capture perceptions about appearance, verbal and non-verbal behaviours of the robot and exposure to technology. The findings from these studies will be consolidated to define interaction and design strategies for the social robot.

2.2 WP2 - Development of autonomous capabilities for the social robot, *Year 2, 3*

WP2 will focus on developing the hardware and software capabilities for the social robot informed by the findings from WP1. This WP is sub-divided into 3 main components, physical design, perception and synthesis. The physical design and appearance of the robot will be refined following feedback from focus group in WP1 and the new design will be fabricated using 3D printing facilities available at Glasgow University. The robot will be powered using cost-effective computers such as Raspberry Pi and smart phones for screen on the robot to display graphical/educational contents relevant to handwashing.

Perception capabilities will be developed using a camera as the main input sensor to keep the design cost effective. The challenge is to recognise hand gestures and behaviour cues in outdoor light sensitive and unstructured environment due to diverse physical setups of handwashing stations in different schools. To determine the quality of handwashing, motion detection within a region tightly cropped into the area over the water tap will be developed. Evaluation will be carried out using the video data gathered from WP1 to check the feasibility for training machine learning algorithms and facial analysis software to asses recognition of behaviour cues (e.g. smiles, head pose) and quality of handwashing, for example the 6 steps of the WHO hand hygiene technique (hand movement).[19] I am collaborating with Prof. Gerard Lacey, Associate Professor in Graphics & Vision at Trinity College Dublin and the CEO & Co-Founder of SureWash (www.surewash.com). SureWash provides state-of-the-art computer vision technology for hand hygiene training in indoor environments to WHO standards to hospitals globally. Prof. Lacey will be a scientific advisor for this research in the area of computer vision technology and system performance evaluation. It is to be noted that the market leading SureWash system is expensive (£30,000), non-portable, uses depth sensors which only work in indoor environments and has limited interaction capabilities, so is therefore not suited for this research which aims to develop a low-cost portable system ($\approx$ US $ 250). I will have a PhD student working on the vision component of the system. The overall perception system setup will combine computer vision and wireless infrared motion sensors register children passing by the toilet, approaching the handwashing station.

On synthesis side, I will incorporate the findings from WP1 into multimodal affective feedback strategies. Both verbal and non-verbal strategies for the social robot using speech, sounds, eye tracking and graphical mouth using the screen on the robot will be developed. The verbal feedback will be delivered in the local regional language the children can understand. Child-like and gender neutral voices are most effective in child-robot interaction so we will incorporate that in our speech design.[20] As there is lack of text-to-speech synthesis systems for Indian regional languages, human voice recordings can be manipulated by shifting the pitch of the sounds file to resemble that of a child whose gender is not apparent in the voice to avoid gender and age perception bias.

2.3 WP3 Field studies, *Year 3, 4*

The first phase of WP3 will involve pilot testing the robot developed in WP2 in 2 rural schools to evaluate the system performance (perception accuracy) and address technical defects of the social robot. Following an iterative design methodology the interaction strategy will be fine tuned following the results from the pilot test. The final system will be incorporated into 5 robots for deployment. Extensive field studies will be carried out in 15-20 rural schools across different states in India to capture the cultural diversity in regards to perception and influence of the social robot. The aim of the field studies will be to investigate (i) influence, (ii) learning transfer and (iii) sustainability of the intervention. The plan to is to carry out staggered interventions to evaluate sustainability of the handashing behaviour with stepped-wedge design methodology.[21] This methodology could help to mitigate novelty effects imposed by exposure of the intervention due to repeated interactions. In the initial stage to investigate the influence of the social robot, a 4 week intervention will be carried in rural schools. Each study will be divided into 3 phases, (i) pre-robot intervention (baseline, no robot, one week) (ii) robot intervention when the robot will be placed at the handwashing station (2 weeks) (iii) post-robot when the robot is removed (one week). In all 3 phases handwashing video data will collected by placing an overhead (capturing handwashing) and front (capturing interaction) cameras near the handwashing station and pre-post questionnaires will be used as described in WP1. Learning transfer will be measured by analysing the handwashing behaviour by manually annotating each handwashing session using BORIS software and system logs. Objective evaluation on the quality of handwashing will be measured by how many steps the children carried out of the 6 steps of handwashing[19] and the duration, frequency of handwashing during critical moments such as before meals and after use of toilet. We will analyse of verbal and non-verbal behaviours that positively correlate with desirable action from the participant for e.g. responding to the instructions from the robot and their reaction time. The synthesis of the results will also benefit from taxonomy of specific techniques to change behaviour.[22] In the final stage, video data from schools will be collected without the robot 6 months after the initial study to measure if the intervention had led to habit formation (sustainability). Effort will be made to collect data from schools to measure the infection-related absenteeism pre and post studies to analyse the overall effect and sustainability of the intervention.

2.4 WP4 - Consolidating results, dissemination and exploring other use cases, *Year 5*

Meta analysis of the results from all field studies will be consolidated into 3 journal publications such as International Journal for Social robotics, Computers & Education and Open Access journals (Lancet Global Health). The main outcome from the meta analysis could provide new understanding how children rationalise their behaviour and be useful in designing appropriate interventions strategies using social robots that influence the target subjects into adopting the decision to perform handwashing behaviour. Results and papers will be further disseminated through social media channels, press releases, local meetings, workshops in local schools in Glasgow, seminars and events such as Global Handwashing Day and science festivals in Edinburgh and Glasgow. During this phase having connected to rural communities other use-cases where social robots could be used as a tool for influencing behaviour change will be investigated by means of unstructured interviews with stakeholders. The areas where social robots can be influential will be centred around UN's sustainable goals but not limited to topics, Good Health & Well-being, Quality Education, Addiction awareness, Gender Equality, Clean Water and Sanitation.
